[2]Department of Rheumatology, St. Margaret Clinic, Budapest, Hungary.

***Corresponding Author:** Miklós Bély M.D., Ph.D., D.Sc. Acad. Sci. Hung, Hospital of the Order of the Brothers of Saint John of God in Budapest, Hungary, Department of Pathology, H- 1027 Budapest, Frankel L. 17-19, Hungary.*

Abstract

*The **aim** of this study was to determine the demographics of **s**ystemic **AA a**myloidosis syndrome (**sAAa**), and **h**epatic **AA a**myloidosis (**hAAa**) in rheumatoid arthritis (**RA**), to assess the predictive clinical laboratory parameters.*

***Patients (autopsy population) and Methods:** The demographics and clinical laboratory parameters were analyzed based on **152** autopsy patients with **RA**. **RA** was confirmed clinically according to the criteria of the American College of Rheumatology (**ACR**). The patients were treated and died in one institute (National Institute of Rheumatology, Budapest, Hungary) between 1969 and 1992.*

*The **sAAa** and **hAAa** was specified histologically, based on evaluation of five organs (kidneys, heart, pancreas, lungs, and liver).*

Amyloid A deposition in different tissue structures of various organs was diagnosed histologically according to Romhányi, by a modified (more sensitive) Congo red staining.

*The correlations were determined by the Student (Welch) t-probe, comparing the age, sex, onset of **RA**, duration of disease, and classic laboratory parameters at the last hospitalization with or without **sAAa** or **hAAa**.*

***Results and Conclusions:** Amyloidosis may develop in both sexes and at any time of the disease.*

The diagnostic values of the discussed laboratory parameters are limited, and none are specific for amyloidosis

*The more or less significant differences between **RA** patients **with** and **without sAAa** show the impaired function of the kidneys or are connected to the basic disease only.*

*There is no significant difference in classic laboratory parameters between cohorts of **RA** patients **with sAAa** and **hAAa**.*

*For exact diagnosis of amyloidosis a biopsy is needed using an „appropriate staining procedure". Gingival or rectal biopsies are suggested. The increased erythrocyte sedimentation rate associated to laboratory parameters of impaired renal function arises the possibility of **hAAa**, and especially in hepatomegaly, a liver biopsy may be considered to confirm **hAAa**.*

Keywords: *Rheumatoid arthritis, demographics, clinical laboratory parameters, systemic AA amyloidosis, AA amyloidosis of the liver*

Abbreviations

RA – Rheumatoid Arthritis

ACA – American College of Rheumatology

AA – **a**myloid **A** protein

AAa – **AA a**myloidosis (**A**myloid **A** protein **a**myloidosis)

sAAa – systemic **AA a**myloidosis

hAAa – **h**hepatic **AA a**myloidosis

SAA – **S**erum **a**myloid **A**

SAP – **S**erum **a**myloid **P** component

ESR – Erythrocyte sedimentation rate

CRP – C reactive protein

A/G ratio – Albumin/**G**lobulin ratio

BUN– blood urea nitrogen

RBC – red blood cells

WBC – white blood cells

GOT– **G**lutamat-**O**xalacetat-**T**ransaminase (=AST – Aspartate transaminase)

GPT – **G**lutamat-**P**iruvat **T**ransaminase (=ALT – Alanine transaminase)

GGT (**gamma GT**) – **G**amma-**G**lutamyl **T**ranspeptidase

LDH – **L**actate **De**h**y**drogenase

DMARDs– Disease **M**odifying **A**ntirheumatic **D**rugs

TNF-α – **T**umour **N**ecrosis **F**actor alpha (**α**)

CoD – Cause of death

U – Uremia

Cl+ – clinically diagnosed

Cl- – clinically not diagnosed

ND – No Data available

NS - Not Significant

SD – Standard **D**eviation

Introduction

Amyloidosis syndromes are systemic or localized disorders characterized by the extracellular deposition of chemically heterogeneous fibrillar proteins. The amyloidosis syndromes are named according to these fibrillar proteins [1, 2]. After **a**myloid **A** protein (**AA**) deposits the disease is named **AA a**myloidosis (**A**myloid **A** protein **a**myloidosis – **AAa**). The precursor of amyloid A protein fibrils is the **s**erum **a**myloid **A** (**SAA**) polypeptide [1, 2]. **SAA** is produced by the liver, spread via the bloodstream, and is deposited in target organs throughout the body, leading toa **s**ystemic **AAa** syndrome (**sAAa**). All forms of systemic amyloidosis are connected to the circulation, and all forms of amyloidosis not connected to the circulation are isolated (localized, organ or tissue limited) [3, 4, 5]. **sAAa** is related to the cardiovascular system, and **h**epatic **AA a**myloidosis (**hAAa**) is connected with it [6].

The **aim** of this study was to determine the demographics of **sAAa** and **hAAa** in **RA**, to assess the predictive clinical laboratory parameters for severe or mild **sAAa** and **hAAa**.

Patients (Autopsy Population) and Methods

The demographics and clinical laboratory parameters were analyzed based on **152** autopsy patients with rheumatoid arthritis (**RA**). **RA** was confirmed clinically according to the criteria of the American College of Rheumatology (**ACR**) [7]. The patients were treated and died in one institute (National Institute of Rheumatology, Budapest, Hungary) between 1969 and 1992 in an era of steroid and disease-modifying antirheumatic drugs (**DMARDs**), before introduction of biological therapy (anti-**TNF-α** treatment, etc.).

The **sAAa** and **hAAa** was specified histologically, based on evaluation of five organs (kidneys, heart, pancreas, lungs, and liver).

Amyloid A deposition in different tissue structures of various organs was diagnosed histologically according to Romhányi [8] by a modified (more sensitive) Congo red staining [9]. The prevalence (existence) and severity (extent) of amyloid A deposition were evaluated microscopically by semi-quantitative visual estimation on a 0 to 3 plus scale, based on the number of involved bloody vessels or tissue structures/light microscopic field x40 objective lens of an Olympus BX51 polarizing microscope.

Footnote

Semi-objective score system of amyloid A deposition: "**0**" – no amyloid deposits, "**1**" –sporadic, minimal amyloid deposits in different tissue structures, "**2**" – less than five involved tissue structures, "**3**" – five or more involved tissue structures/light microscopic field x40 objective lens. **Remark**: in case of medium size arteries and veins this corresponds to the absolute number of involved medium size vessels of a tissue sample, e.g. "**0**" none, "**1**" only one,"**2**" less than five, "**3**" 5 or more than five medium size vessels/tissue sample with a x20 objective lens.

The correlations were determined by the Student (Welch) t-probe [10], comparing the age, sex, onset of **RA**, duration of disease, and classic laboratory parameters {Latex, Waaler-Roose values, ESR, CRP, serum albumin/globulin ratio, serum electrophoresis (albumin, alpha-1-globulin, alpha-2-globulin, beta-globulin, gamma-globulin), RBC, hemoglobin, WBC, blood urea nitrogen (BUN), serum creatinin, serum potassium and sodium values, urine specific gravity, proteinuria, urine sediment (RBC, WBC), serum bilirubin, LDH, GPT, GGT, blood sugar, and diastase values, systolic and diastolic blood pressure} at the last hospitalization with or without **sAAa** or **hAAa**, and with "**mild**" (**< 0.8** / patient) or "**severe**" amyloid A deposits (**0.8 ≤** / patient).

Footnote

GPT – **G**lutamate-**P**iruvate **T**ransaminase (=ALT – Alanine transaminase), or immunological parameters (**SAA**, serum amyloid P component – **SAP**, etc. were not analyzed between 1969 and 1992 in our Institute.

Results

sAAa complicated **RA** in **32** (21.05 %) of 152 patients. **sAAa** was histologically excluded in **120** (78.95 %) of 152 **RA** patients.

Seventeen (53.125 %) of 32 patients had "**slight** (**mild**)" amyloidosis (with average amyloid A deposits / patient **<0.8**), involving only a few tissue structures in the kidneys, heart, pancreas, and lung.

Fifteen (46.875 %) of 32 patients revealed "**marked** (**severe**)" amyloidosis (with average amyloid A deposits / patient **0.8 ≤**), massively involving many tissue structures of the kidneys, heart, pancreas, and lung.

Branches of blood vessels of different calibers and various tissue structures of the liver were involved in **26** (81.25 % of 32, 17.11 % of 152) cases; **hAAa** was histologically excluded in **6** (18.75 % of 32) patients with **sAAa**.

In **15** (46.875 %) of 26 **RA** patients with **hAAa** the average amount of amyloid A deposits of the liver was less than **<0.8**, and was regarded "**slight** (**mild**)", and in **11** (34.375 %) of 26 patients it was more than **0.8 ≤**, and was considered "**marked** (**severe**)".

In Table 1 are summarized the demographics, onset and duration of disease of the **total population** (n=**152**), **with mild** (n=**17**) and **severe** (n=**15**) **sAAa** (n=**32**), **without sAAa** (n=**120**), **with mild** (n=**15**) and **severe** (n=**11**) **hAAa** (n=**26**), and **without** (n=**6**) amyloid A deposits of the **liver**.

Table1. *Sex, mean age with SD, range, onset and disease duration (in years) of 152 RA patients with or without sAAa and hAAa*

(Extended data published by Miklós Bély and Ágnes Apáthy in: Archives of Gastroenterology and Hepatology, 2020,3.2: 1:26 [6])

Sex	Number of autopsies	Mean age in years at death ± SD	Range (in years)	Mean age at onset of disease ± SD	Disease duration (in years) mean ± SD

Glossary to Table 1

RA – Rheumatoid **A**rthritis
sAAa – systemic **AA a**myloidosis
hAAa – hepatic **AA a**myloidosis (amyloid A deposits in the liver)
SD – Standard **D**eviation

There was **no significant difference** in **survival time** (63.25 ys versus 66.49 ys; p< 0.290 – NS), **onset** (48.17 ys versus 52.37 ys; p< 0.284 – NS), and **duration** of **disease** (16.00 ys versus 13.81 ys; p< 0.303 – NS), between **RA** patient cohorts **with sAAa** (n=32) and **without sAAa** (n=120), **with sAAa** (n=32) and **with hAAa** (n=26) or **with hAAa** (n=26) and **without hAAa** (n=6), neither **females** nor **males** (except the age of patients at death **with hAAa** and **without hAAa**; the patients **with hAAa** died earlier, than the patients **without hAAa** (61.31 ys versus 71.67 ys; **p <0.040**) (Tables 1 and 2).

Comparing **age, sex, onset of RA**, and **duration of disease** at the time of death **RA** started earlier in patients **with severe sAAa** (n=15) in comparison to the patients **with mild sAAa** (n=17) (37.67 ys versus 55.59 ys; p<0.095 – NS) or compared to the patients **without sAAa** (n=120) (37.67 ys versus 52.37 ys; p<0.065 – NS).

Disease duration **with severe** systemic amyloid A deposition was significantly longer in comparison to the patients **with mildsAAa** (19.58 ys versus 13.47 ys; p< **0.014**) or compared to patients **without sAAa** (19.58 ys versus 13.81 ys; p< **0.025**).

The patients **with severe sAAa** (n=15) died significantly earlier in comparison to the patients **with mildsAAa** (n=17) (56.67 ys versus 69.06 ys; p< **0.032**) or compared to the patients **without sAAa** (n=120) (56.67 ys versus 66.49 ys; p<0.061 – NS) (Tables 1 and 2).

Comparing **age, sex, onset of RA**, and **duration of disease** at the time of death **RA** started earlier in patients **with severe hAAa** (n=11) in comparison to the patients **with mild hAAa** (n=15) (35.89 ys versus 55.50 ys; p<0.804 – NS) or compared to the patients **without hAAa** (n=6) (35.89 ys versus 49.50 ys; p<0.148 – NS).

Disease duration **with severe hAAa** was significantly longer in comparison to the patients **with mild hAAa** (18.89 ys versus 11.50 ys; p< **0.035**) or compared to patients **without hAAa** (11.89 ys versus 22.17 ys; p<0.496 – NS).

The patients **with severe hAAa** (n=11) died significantly earlier in comparison to the patients **with mild hAAa** (n=15) (53.82 ys versus 66.80 ys; p<0.079 – NS) or compared to the patients **without hAAa** (n=6) (53.82 ys versus 71.67 ys; p< **0.024**) (Tables 1 and 2).

Demographics, onset and duration of disease of female and male **RA** patients **with** (n=32) and **without sAAa** (n=120), are summarized in Figures 1.a-e – 2.a-e

Glossary to Table 2
RA – Rheumatoid **A**rthritis
sAAa – systemic **AA a**myloidosis (amyloid A deposits in the kidneys, heart, pancreas, and lungs)
hAAa – hepatic **AA a**myloidosis (amyloid A deposits in the liver)

The patients **with sAAa** (n=32) were **anemic**, with significantly lower levels of **hemoglobin** (7.311 g/l vs 8.637 g/l; p<**0.011**), and showed **decreased renal function**: they had **higher levels** of blood urea

nitrogen (**BUN**) (17.57 mmol/l vs 9.491 mmol/l; p <**0.021**), serum **creatinine** (182.44 µ mol/l vs 96.373 µ mol/l; p <**0.008**), and lower levels of serum **sodium** (138.27 mmol/l vs 140.62 mmol/l; p <**0.027**), and were accompanied by **proteinuria** (1.821 "+" vs 0.806 "+"; p<**0.003**) compared to the patients **without sAAa** (n=120).

Urine specific gravity (1011.37 g/ml vs 1015.65 g/ml; p<**0.011**), and serum **bilirubin** values (7.435 µmol/l vs 11.041 µmol/l; p<**0.001**) were **lower** in patients **with sAAa** compared to the patients **without sAAa**.

Massive (severe) sAAa (n=15) was accompanied by significantly **lower levels** of **hemoglobin** (6.258 g/l vs 8.15 g/l; p<**0.019**), **higher levels** of serum **creatinine** (252.61 µ mol/l vs 127.31 µ mol/l; p <**0.042**), serum **potassium** (5.35 µmol/l vs 4.50 µmol/l; p<**0.011**), and was accompanied by **proteinuria** (2.833 "+" vs 1.06 "+"; p<**0.002**), compared to the patients **with mild sAAa** (n=17).

Massive (severe) sAAa (n=15) was accompanied by significantly **lower levels** of **hemoglobin** (6.258 g/l vs 8.637 g/l; p<**0.000043**), **higher levels** of blood urea nitrogen (**BUN**) (18.43 mmol/l vs 9.491 mmol/l; p <**0.003**), serum **creatinine** (252.61 µ mol/l vs 96.373 µ mol/l; p <**0.009**), and was accompanied by **proteinuria** (2.833 "+" vs 1.33 "+"; p<**0.000324**), compared to the patients **without sAAa** (n=120).

Urine specific gravity (1011.63 g/ml vs 1015.65 g/ml; NS – p<0.111), and serum **bilirubin** values (7.435 µmol/l vs 11.041 µmol/l; p<**0.001**) were **lower** in patients **with massive (severe)sAAa** compared to the patients **without sAAa**.

There was no significant difference in classic laboratory parameters between cohorts of **RA** patients **with sAAa** and **hAAa**.

The patients **with hAAa** (n=26) had significantly **higher levels** of serum **creatinine** (214.09 µ mol/l vs 82.22 µ mol/l; p <**0.003**), and were accompanied by **proteinuria** (2.09 "+" vs 0.83 "+"; p<**0.049**) compared to the patients **without hAAa** (n=6).

Massive (severe) hAAa (n=11) was accompanied by significantly **lower levels** of **hemoglobin** (5.87 g/l vs 8.12 g/l; p<**0.009**), **higher levels** of serum **potassium** (5.45 m mol/l vs 4.59 mmol/l; p <**0.031**), and was accompanied by **proteinuria** (3.28 "+" vs 1.27 "+"; p<**0.001**), compared to the patients **with mild hAAa** (n=15).

Massive (severe) hAAa (n=11) was accompanied by significantly **higher levels** of blood urea nitrogen (**BUN**) (19.37 mmol/l vs 12.18 mmol/l; p <**0.043**), serum **creatinine** (264.41 µ mol/l vs 82.22 µ mol/l; p <**0.014**), **serum potassium** (5.45 mmol/l vs 4.47 mmol/l; p<**0.031**), and was accompanied by **proteinuria** (3.28 "+" vs 0.83 "+"; p<**0.002**), compared to the patients **without hAAa** (n=6).

The relevant clinical laboratory parameters of **RA** patients **with mild** or **severe sAAa** and **without sAAa**, furthermore **with mild** or **severe hAAa** and **without hAAa** are summarized in Table 3.1 and Figures 3.1-3.2.

Table3.1. *Significantly different or characteristic clinical laboratory parameters of RA patients with and without sAAa or hAAa*

Parameters ± SD	Normal range	With sAAa n=32 of 152	With mild sAAa n=17 of 32	With severe sAAa n=15 of 32	Without sAAa n=120 f 152

Glossary to Table 3.1

sAAa – systemic **AA a**myloidosis (amyloid A deposits in the kidneys, heart, pancreas and lungs)

hAAa – hepatic **AA a**myloidosis (amyloid A deposits in the liver)

SD – Standard **D**eviation

Figure3.1. Significantly different or characteristic clinical laboratory parameters of RA patients with mild or severe sAAa and without sAAa

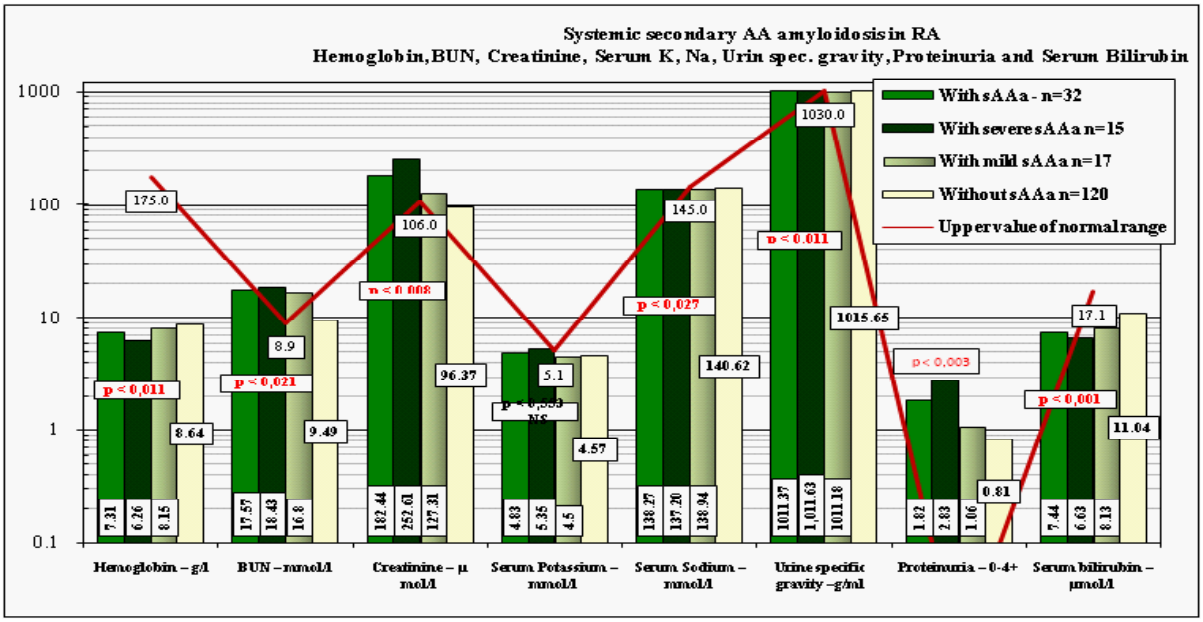

Figure 3.1*. *There was a significant relationship between RA patients with mild or severe sAAa and without sAAa: the RA patients with sAAa had significantly lower levels of hemoglobin (7.311 g/l vs 8.637 g/l; p<0.011), and showed decreased renal function: they had higher levels of blood urea nitrogen (BUN) (17.57 mmol/l vs 9.491 mmol/l; p <0.021), serum creatinine (182.44 μ mol/l vs 96.373 μ mol/l; p <0.008), and lower levels of serum sodium (138.27 mmol/l vs 140.62 mmol/l; p <0.027), serum bilirubin (7.435 μmol/l vs 11.041 μmol/l; p<0.001), and were accompanied by proteinurea (1.821 "+" vs 0.806 "+"; p<0.003) compared to the patients without sAAa.*

**Figure 3.1 indicates only the "p" values between sAAa and without sAAa.*

Figure3.2. Significantly different or characteristic clinical laboratory parameters of RA patients with mild or severe hAAa and without hAAa

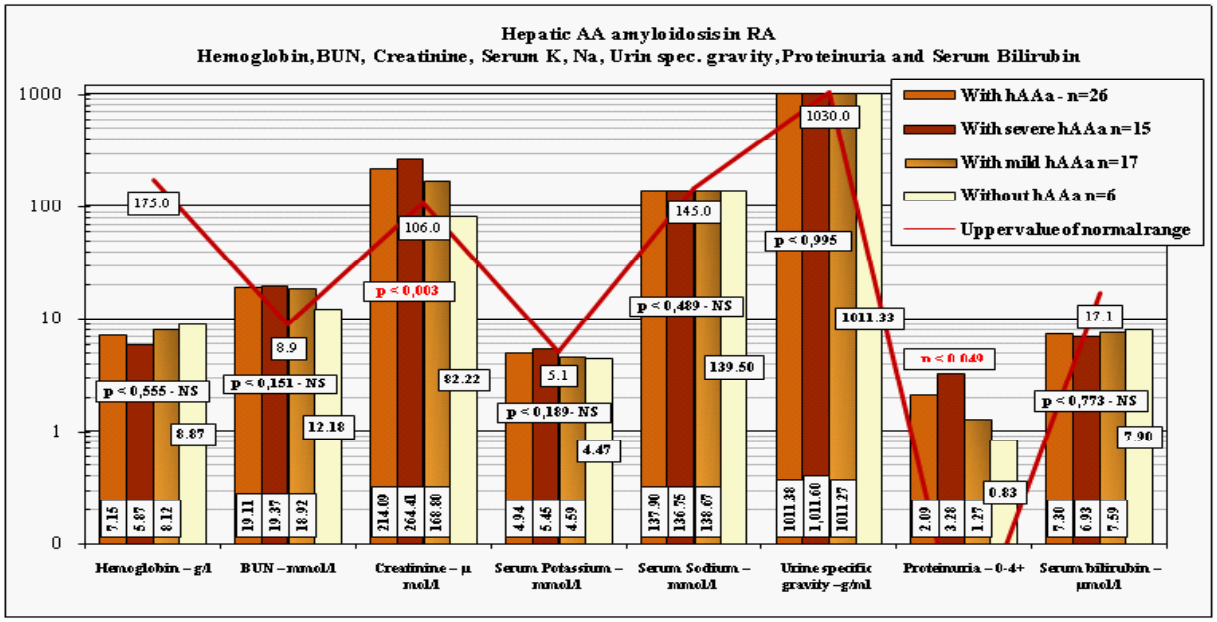

Figure 3.2. There was no significant difference in clinical laboratory parameters between RA patients with (n=26) and without hAAa (n=6), except serum creatinine level (214.09 μ mol/l vs 82.22 μ mol/l; p <0.003), and proteinurea (2.09 "+" vs 0.83 "+"; p<0.049).*

** Figure 3.2 indicates only the "p" values between hAAa and without hAAa.*

Table 3.2 summarizes the statistical correlations ("p" values of significance) of **RA** patient cohorts **with mild** or **severe sAAa** and **without sAAa**, furthermore **with mild** or **severe hAAa** and **without hAAa**.

Table3.2. *The statistical correlations ("p" values of significance) between RA patients with and without sAAa or hAAa*

Figures 3-5 illustrate Amyloid A deposition in the kidneys representing different stages of **sAAa**.

The original magnification (O) of electron microphotographs (elements of montage) correspond to the 60x90 mm negatives

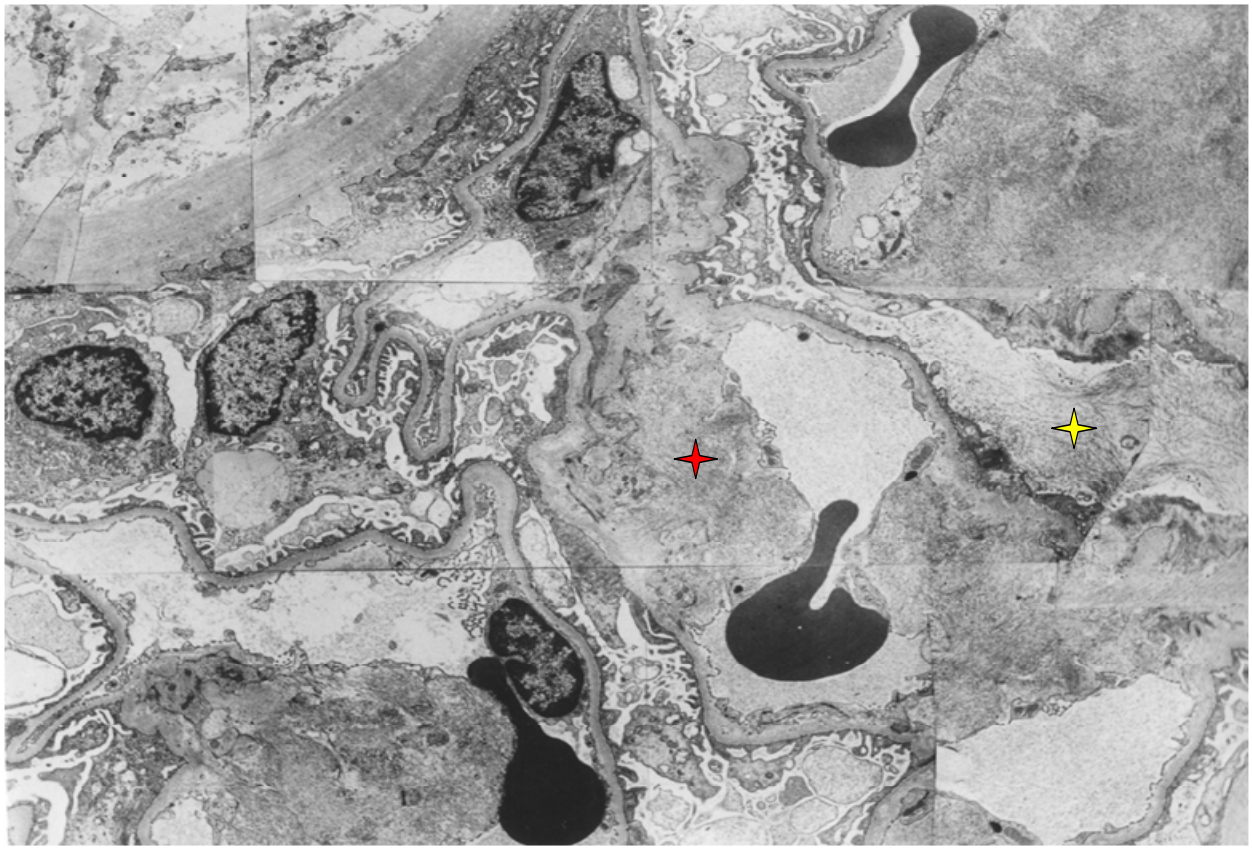

Figure3. *Electron micrograph (montage)*
Rheumatoid arthritis, kidney, early stage of amyloid A deposition
Moderate subendothelial (red star), and mesangial (yellow star) amyloid deposits, damaged endothelial cells. Early, advanced and late stages (see next Figure 4 and Figure 5) of amyloid deposits side by side in different glomeruli in the same kidney demonstrate the progressive accumulation of amyloid deposits,
O: x2600.
CL – capillary lumen

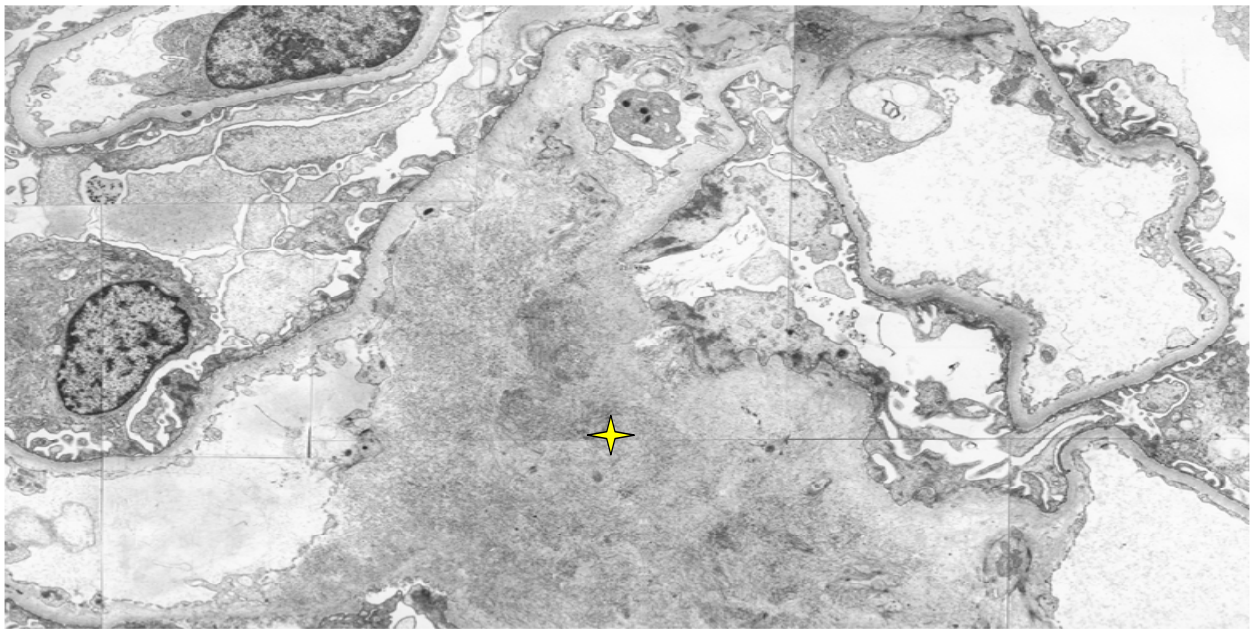

Figure4. *Electron micrograph (montage)*
Rheumatoid arthritis, kidney, advanced stage of amyloid A deposition
Moderate subendothelial and massive mesangial amyloid deposits of different density (yellow star), damaged endothelial cells, and podocytes, side by side in the same glomerulus demonstrate the progressive accumulation of amyloid deposits,
O: x2600.

Figure5. *Electron micrograph (montage)*
Rheumatoid arthritis, kidney, late stage of amyloid A deposition, with massive subendothelial (red star) and mesangial (yellow star) amyloid deposits
The capillary is lined by damaged endothelial cells and the podocytes are degenerated.
Early, advanced and late stages of amyloid deposits side by side in different glomeruli in the same kidney demonstrate the progressive accumulation of amyloid deposits,
O: x2600.

Figures 6 and 7 demonstrate the extent of amyloid A deposits in the liver by traditional HE and Congo red staining, viewed by light microscopy and under polarized light respectively.

Original magnifications correspond to the 24x36 mm transparency slide; the correct height: width ratio is 3:2. The printed size may be different; therefore it is necessary to indicate the original magnifications.

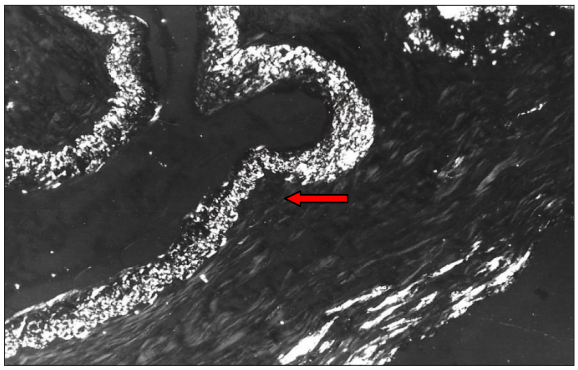

Figure7c

Figure6a-c. *Rheumatoid arthritis, liver, advanced stage of hAAa*

Arteriole, small artery (arrowhead yellow), medium size artery (arrowhead red) and small (star yellow) and medium size (star red) veins, amyloid A deposits are within the walls of blood vessels

Collecting biliary duct with subendothelial amyloid A deposits in basal lamina

(a) HE traditional staining and ligh microscopy, x50, (b) same as (6a) x125, (c) same as (6a) x200

Figure7a-c. *Rheumatoid arthritis, liver, advanced stage of hAAa*

Amyloids A deposits within the wall of blood vessels, and in basal lamina of collecting biliary duct are birefringent

(a) same as (6a) Congo red staining, without alcoholic differentiation, covered with gum Arabic, viewed under polarized light, x50, (b) same as (6b) x125, (c) same as (6c) x200

Discussion

In our patient cohorts there was **no significant difference** in **survival time**, **onset**, and **duration** of **disease**, between **RA** patient cohorts **with sAAa** and **without sAAa**, **with sAAa** and **with hAAa**, neither in **females** nor in **males**. ***Amyloidosis may develop in both sexes and at any time of the disease*** [6].

Diagnostic values of discussed laboratory parameters are limited. No blood test is specific for amyloidosis [11].

In some cases the values of clinical-laboratory parameters mentioned in the pertinent literature remained in the normal range, for example serum albumin (35-50 g/l), total serum bilirubin (5.0-17.1 μmol/l), serum potassium (3.70-5.10 mmol/L), sodium (135-145 mmol/lL, urine specific gravity between 1000 and 1030), etc., which reduce the clinical significance of these parameters, and only their graduall impairment may suggest a trend.

There was no significant difference in classic laboratory parameters between cohorts of **RA** patients **with sAAa** and **hAAa**, including the inflammatory laboratory parameters, and the characteristic liver enzymes.

The more or less significant differences between **RA** patients **with** and **without sAAa** are connected with **decreased renal function**; the **higher** levels of blood urea nitrogen (**BUN**) (17.57 mmol/L vs 9.49 mmol/L, p < **0.021**), serum **creatinine** (182.44 μmol/L vs 96.37 μmol/L vs, p < **0.008**), serum **potassium** (4.83 mmol/L vs 4.57 mmol/L, p < 0.533 – NS), and **proteinuria** (1.82 "+" vs 0.81 "+", p<**0.003**), with **lower** levels serum **sodium** (138.27 mmol/L vs 140.62 mmol/L, p <**0.027**), and **urine specific gravity**, namely the less concentrated urine (1011.37 g/L vs 1015.65 g/L, p <**0.001**) show the impaired function of the kidneys only, like other causes of nephrotic syndrome. ***The mentioned clinical-laboratory parameters are not specific for* sAAa**, and ***they imply more or less only renal impairment***.

Progression of renal amyloidosis is associated with severe proteinuria or nephrotic syndrome [12]. Indeed, several authors call attention the importance of proteinuria in the early literature [13, 14, 15].

The rate of **proteinuria** in our autopsy population proved to be of prognostic value, and may indicate the severity of **sAAa**; the rate of proteinuria correlated with the severity of **sAAa** (**severe** vs **mild sAAa**: 2.83 "+" vs 1.06 "+"; p<**0.002**; **severe sAAa** vs **without sAAa**: 2.83 "+" vs 0.81 "+"; p<**0.00032**), based on the increasing levels of significance. The elevated serum **creatinine** level may also indicate progression of renal amyloidosis (**severe** vs **mild sAAa**: 252.61 μmol/L vs 127.31 μmol/L, p<**0.042**; **severe** vs **without sAAa**: 252.61 μmol/L vs 96.37 μmol/L, p<**0.009**).

The differences were marked in **hemoglobin** levels (**severe** vs **mild sAAa**: 6.26 g/L vs 8.15 g/L, p <**0.019**; **severe** vs **without sAAa**: 6.26 g/L vs 8.64 g/L, p <**0.000043**), and in serum **bilirubin** values as well (**severe** vs **mild sAAa**: 6.63 μmol/L vs 8.13 μmol/L, p<0.328; **severe** vs **without sAAa**: 6.63 μmol/L vs 11.04 μmol/L, p<**0.001**).

The low levels of **hemoglobin** (7.31 g/L vs 8.64 g/L, p <**0.01**), and the subsequent serum **bilirubin** values (7.44 μmol/L vs 11.04 μmol/L vs, p <**0.001**) may underline the existence of **sAAa**, but likewise are not specific for amyloidosis.

Anemia may be regarded as a kind of non-hemolytic anemia only [16] accompanied by lower levels of serum **bilirubin** (degradation product of hemoglobin).

Increased **ESR** (81.227 mm/h vs 48.667 mm/h, p <**0.003**), and higher levels of **alpha2-globulin** (15.19 % vs 12.90 %, p <**0.048**), may indicate the existence of **hAAa**, in comparison to **RA** patients **without hAAa**.

Erythrocyte sedimentation rate may increase in any inflammation. High values of **alpha2-globulin** are related to the basic inflammatory processes of the disease, and not to amyloid A deposition [17].

More recent laboratory parameters such as serum amyloid A (**SAA**) level were not determined between 1969 and 1992. **SAA** and **CRP** are regarded now the most sensitive indicators for assessing inflammatory activity [18]. **SAA** proteins are produced predominantly by the liver [19]. **SAA** is implicated in several chronic inflammatory diseases, such as rheumatoid arthritis, amyloidosis, atherosclerosis etc. [20]. Prolonged elevation of **SAA** is not specific for amyloidosis, and does not necessarily indicate tissue deposition of amyloid A [17].

Radioactive imaging, using radiolabeled amyloid molecules, i.e. serum amyloid P component (**SAP**)

scintigraphy [21] or positron emission tomography (**PET**) [22] has not yet fullfiled the hopes [23].

For exact diagnosis of amyloidosis biopsy is needed using an „appropriate staining procedure" [24]. We suggest gingival or rectal biopsies in any suspected cases, stained with Congo red according to Romhányi, using an appropriate polarizing microscope with high brightness. In case of increased **ESR**, the possibility of **hAAa** arises, and especially in hepatomegaly, liver biopsy may be considered to confirm **hAAa**.

Conclusions

Amyloidosis may develop in both sexes and at any time of the disease.

The diagnostic values of the discussed laboratory parameters are limited, and none are specific for amyloidosis

The more or less significant differences between **RA** patients **with** and **without sAAa** show the impaired function of the kidneys or are connected to the basic disease only.

There is no significant difference in classic laboratory parameters between cohorts of **RA** patients **with sAAa** and **hAAa**.

For exact diagnosis of amyloidosis a biopsy is needed using an „appropriate staining procedure". Gingival or rectal biopsies are suggested [3]. In case of increased **ESR**, the possibility of **hAAa** arises, and especially in hepatomegaly a liver biopsy may be considered to confirm **hAAa**.
